GENERAL INTRODUCTION

All the applications of quantum mechanics that you would have been taught up to now is based on the Schrodinger equation. This equation is deduced from the Hamiltonian formalism of classical mechanics, and so has all the invariance properties of the Hamiltonian. In particular, it is invariant under Galilean transformations. But the Schrodinger equation is not invariant under Lorentz transformations, as required by the principle of relativity. Thus, this theory will correctly describe phenomena only when the velocities of the particles involved are small compared to that of light: $v \ll c$. For example, all phenomena concerning the interaction of light and matter, such as the emission, absorption or scattering of photons, is outside the framework of non-relativistic quantum mechanics.

At first sight, one might expect that the change to a relativistic theory is possible by a direct generalisation of the formalism of non-relativistic quantum mechanics. But further consideration shows that a logically complete relativistic theory cannot be constructed without invoking new physical principles. One of the main difficulties comes from the fact that the law of conservation of the number of particles ceases to be true in general. This is due to the equivalence between mass and energy:

$$E = mc^2,$$

one of the most important consequences of the theory of relativity. Together with the Heisenberg uncertainty principle,

$$\Delta E \Delta t \sim \hbar ,$$

this implies that energy fluctuations in the course of a sufficiently short observation can appear as additional matter. Hence, one needs a formalism where the number of particles is not fixed. The concept of a single-particle wave function has to be replaced by the concept of a quantum field varying over space-time. This is why the name ‘quantum field theory’ is usually given to relativistic quantum mechanics. Although this theory is not quite logically complete, there is very good experimental evidence for it, particularly for quantum electrodynamics (QED).

CONTENTS

General Introduction	1
Chapter 1. Relativistic quantum mechanics	3
1.1 Relativistic notation	3
1.2 Lorentz group	6
1.3 Klein–Gordon equation	8
1.4 Dirac equation	11
1.5 Relativistic covariance	13
1.6 Free particle solutions and their interpretation	17
1.7 Interaction with electromagnetic field	20
1.8 References and further reading	22
Chapter 2. Feynman path-integral formulation of quantum mechanics	23
2.1 Classical action	23
2.2 Quantum mechanical propagator	24
2.3 Schrödinger equation	26
2.4 Free-particle propagator	30
2.5 Harmonic oscillator	33

2.6 Stationary states	35
2.7 Perturbation theory	38
2.8 Momentum representation	41
2.9 References and further reading	42
Chapter 3. Canonical quantisation	44
3.1 Classical mechanics and field theory	44
3.2 Real scalar field	48
3.3 Complex scalar field	55
3.4 Spinor field	57
3.5 Covariant commutation relations	59
3.6 Electromagnetic field	64
3.7 References and further reading	68
Chapter 4. Interacting fields	69
4.1 Asymptotic conditions	70
4.2 Expression for S -matrix	73
4.3 Elements of the S -matrix	75
4.4 ϕ^4 theory	83
4.5 Calculation of cross-section	86
4.6 Scattering of spin- $\frac{1}{2}$ particles	89
4.7 Processes involving photons	92
4.8 References and further reading	93
